RaceDay Event Management System

Project Overview

- RaceDay: What is it?
- A full-stack online platform designed for road events in South Africa
- encourages bike, walking, and running competitions
- solves the issue with spreadsheet-based and paper-based management
- Two roles for users: Participant and Organizer
- Included in Part 1 are:
- Designing a database with an Entity Relationship Diagram (ERD)
- Planning table for API endpoints
- Database script for SQL Server
- Workflow for GitHub CI/CD validation

System Roles

- ORGANIZER
 - Make, modify, and remove events
 - For every event, add and manage racing categories.
 - Record and disseminate participant outcomes
 - View all of their event enrollments
- A PARTICIPANT
 - Register and look through forthcoming events.
 - Select a race category to enter events.
 - See their own enrollment records
 - Monitor their individual race performance and outcomes.

Database Design

- The database contains six tables:
- User: keeps track of account information, email, password, name, and role;
- Event: keeps track of the event's name, location, dates, and organizer.
- RouteInfo keeps track of each event's distance, map link, and weather information;
- Category keeps track of race types, including 10 and 21 kilometers, along with price and limit;
- Enrollment keeps track of which participants entered which category;
- Result keeps track of each completed entry's position and finish time.
- Each table has a primary key, which is a unique ID. Foreign keys are used to join tables together so that data remains accurate and connected.
- Entity Relationship Diagram (ERD) on Slide 5

Entity Relationship Diagram

- The connections between the tables:
- Many events can be created by a single organizer.
- There is only one RouteInfo per Event.
- There might be multiple categories for a single event.
- Through enrollment, a single participant can enter many categories.
- A single enrollment may provide a single outcome.

API Endpoint Plan

- The API will adhere to common REST guidelines:
- To read and see data, utilize GET.
- To generate new records, use POST.
- PUT is used to update records that already exist.
- DELETE is used to get rid of records.
- Endpoints that are planned include:
- Create a new account, log in, and view or modify your user profile.
- List, add, modify, and remove Events
- Control the categories for every event.
- Participate in events and see entries
- Keep track of and view the race results
- Each endpoint provides usage guidelines, such as "Organizer only," "Participant only," or "open to everyone."

Github

- Every file is kept on GitHub at [Lindokuhle56/RaceDay](#)
- Organization of folders:
- The SQL script, API plan, and ERD image are located in the docs folder. The CI/CD file README is located in the github/workflows folder. The primary project information file is called md.
- An automatic checker is the CI/CD workflow. Each time I upload a file, it verifies:
- All necessary Part 1 files are located in the appropriate locations.
